# 0.1 Introduction to qm

Package version: 0.5

The qm package provides functions and standard definitions to solve quantum mechanics problems in a finite dimensional Hilbert space. One can calculate the outcome of Stern-Gerlach experiments using the built-in definition of the Sx, Sy, and Sz for arbitrary spin, e.g.  $s=\{1/2, 1, 3/2, \ldots\}$ . One can create ket vectors with arbitrary but finite dimension and perform standard computations.

With this package it is also possible to create tensor product states for multiparticle systems and to perform calculations on those systems.

The qm package was written by E. Majzoub, Univ. of Missouri. Email: majzoube-at-umsystem.edu

# 0.2 Functions and Variables for qm

 $cvec (a_1, a_2, ...)$  [Function]

cvec creates a column vector of arbitrary dimension. The entries  $a_i$  can be any Maxima expression.

rvec  $(a_1, a_2, ...)$  [Function]

rvec creates a row vector of arbitrary dimension. The entries  $a_i$  can be any Maxima expression.

```
(%i8) rvec(1,2,3);
(%o8) [ 1 2 3 ]
```

 $ket (c_1, c_2, ...)$  [Function]

ket creates a *column* vector of arbitrary dimension. The entries  $c_i$  can be any Maxima expression. If the entries are simple symbols or coefficients of simple functions then they will be declare-ed complex. If one is having difficulty with getting the correct constants declared complex then one is suggested to use the cvec and rvec functions.

bra  $(c_1, c_2, \dots)$  [Function]

bra creates a row vector of arbitrary dimension. The entries  $c_i$  can be any Maxima expression. If the entries are simple symbols or coefficients of simple functions then

they will be declare-ed complex. If one is having difficulty with getting the correct constants declared complex then one is suggested to use the cvec and rvec functions.

ketp (vector) [Function]

ketp is a predicate function that checks if its input is a ket, in which case it returns true, else it returns false.

brap (vector) [Function]

brap is a predicate function that checks if its input is a bra, in which case it returns true, else it returns false.

dag (vector) [Function]

dag returns the conjugate transpose of its input.

#### braket (psi,phi)

[Function]

Given two kets psi and phi, braket returns the quantum mechanical bracket <psi|phi>. The vector psi may be input as either a ket or bra. If it is a ket it will be turned into a bra with the dag function before the inner product is taken. The vector phi must always be a ket.

norm (psi) [Function]

Given a ket or bra psi, norm returns the square root of the quantum mechanical bracket <psi|psi>. The vector psi must always be a ket, otherwise the function will return false.

The following additional examples show how to input vectors of various kinds and to do simple manipulations with them.

```
(%i1) load(qm)$
(%i2) rvec(a,b,c);
(\%02)
                                  [a b c]
(%i3) facts();
(%o3)
             [kind(hbar, real), hbar > 0]
(%i4) bra(a,b,c);
                                  [a b c]
(\%04)
(%i5) facts();
(%o5) [kind(hbar, real), hbar > 0, kind(a, complex),
                   kind(b, complex), kind(c, complex)]
(%i6) braket(bra(a,b,c),ket(a,b,c));
                                       2
(\%06)
                                 c + b + a
(%i7) braket(ket(a,b,c),ket(a,b,c));
(\%07)
               c conjugate(c) + b conjugate(b) + a conjugate(a)
(%i8) norm(ket(a,b,c));
(%08)
            sqrt(c conjugate(c) + b conjugate(b) + a conjugate(a))
```

## 0.2.1 Spin-1/2 state kets and associated operators

Spin-1/2 particles are characterized by a simple 2-dimensional Hilbert space of states. It is spanned by two vectors. In the z-basis these vectors are {zp,zm}, and the basis kets in the z-basis are {xp,xm} and {yp,ym} respectively.

zp, zm, xp, xm, yp, ym

[Function]

Return the ket of the corresponding vector in the z-basis.

Switching bases is done in the following example where a z-basis ket is constructed and the x-basis ket is computed.

# 0.2.2 Pauli matrices and Sz, Sx, Sy operators

sigmax, sigmay, sigmaz [Function]
Returns the Pauli x,y,z matrix.

Sx, Sy, Sz [Function] Returns the spin-1/2 Sx, Sy, Sz matrix.

(%i3) sigmay; 0 ] - %i ] (%o3) ] [ %i ] (%i4) Sy; %i hbar ] Г 0 2 ] (%o4) ] ] [ %i hbar ] 0 2

# 0.2.3 SX, SY, SZ operators for any spin

SX, SY, SZ (s) [Function]

SX(s) for spin s returns the matrix representation of the spin operator Sx, and similarly for SY(s) and SZ(s). Shortcuts for spin-1/2 are Sx,Sy,Sz, and for spin-1 are Sx1,Sy1,Sz1.

Example:

(%i7) SX(1); hbar Г 0 ] 0 ] sqrt(2) hbar hbar (%07) 0 sqrt(2) ] sqrt(2) ] hbar 0 0 ] sqrt(2) ]

# 0.2.4 Expectation value and variance

expect (0,psi) [Function]

Computes the quantum mechanical expectation value of the operator O in state psi, <psi|O|psi>.

qm\_variance (0,psi)

[Function]

Computes the quantum mechanical variance of the operator O in state psi,  $sqrt(\langle psi|O^2|psi \rangle - \langle psi|O|psi \rangle^2)$ .

## 0.2.5 Angular momentum and ladder operators

SP (s) [function]

SP is the raising ladder operator  $S_{+}$  for spin s.

SM (s) [function]

SM is the raising ladder operator  $S_{-}$  for spin s.

Examples of the ladder operators:

(%i4) SP(1):

(70) ~	- \ - / )				
		[ 0	sqrt(2) h	oar 0	]
		[			]
(%o4)		[ 0	0	sqrt(2)	hbar ]
		[			]
		[ 0	0	0	]
(%i5) S	SM(1);				
		[	0	0	0 ]
		[			]
(%o5)		[sq:	rt(2) hbar	0	0 ]
		[			]
		[	0	sqrt(2) hba	ar 0]

# 0.3 Rotation operators

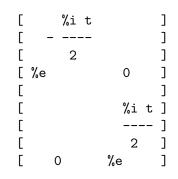

RX, RY, RZ (s,t)

[Function]

RX(s) for spin s returns the matrix representation of the rotation operator Rx for rotation through angle t, and similarly for RY(s,t) and RZ(s,t).

(%i10) RZ(1/2,t);

(%o10)

# 0.4 Time-evolution operator

UU (H,t) [Function]

UU(H,t) is the time evolution operator for Hamiltonian H. It is defined as the matrix exponential matrixexp(-%i\*H\*t/hbar).

## 0.5 Tensor products

Tensor products are represented as lists in Maxima. The ket tensor product |z+,z+> is represented as [tpket,zp,zp], and the bra tensor product <a,b| is represented as [tpbra,a,b] for kets a and b. The list labels tpket and tpbra ensure calculations are performed with the correct kind of objects.

$$ketprod (k_1, k_2, ...)$$

[Function]

ketprod produces a tensor product of kets  $k_i$ . All of the elements must pass the ketp predicate test to be accepted.

#### braprod $(b_1, b_2, \ldots)$

[Function]

braprod produces a tensor product of bras  $b_i$ . All of the elements must pass the brap predicate test to be accepted.

#### braketprod (B,K)

[Function]

braketprod takes the inner product of the tensor products B and K. The tensor products must be of the same length (number of kets must equal the number of bras).

Examples below show how to create tensor products and take the bracket of tensor products.

```
(%i7) zpb: dag(zp);
                                   [10]
(%o7)
(%i8) zmb: dag(zm);
                                   [ 0 1 ]
(%08)
(%i9) K: ketprod('zp,'zm);
                               [tpket, [zp, zm]]
(%09)
(%i10) B: braprod(zpb,zmb);
                         [tpbra, [[ 1 0 ], [ 0 1 ]]]
(%010)
(%i11) B: braprod('zpb,'zmb);
                              [tpbra, [zpb, zmb]]
(%o11)
(%i12) braketprod(K,B);
(%o12)
                                     false
(%i13) braketprod(B,K);
(%o13)
                             (zmb . zm) (zpb . zp)
```
